**Sexy Smells - A case study using preen oil composition of the Dark Eyed Junco**

**Sarah Prescott (University of New Hampshire) and Melissa Haswell (Davenport University)**

### Abstract

This case study invites students to explore the biochemistry and physiology of pheromones using authentic data. The case is based off of research published by Dr. Danielle Whitaker et al. and presents data on the composition of preen oil of the dark eyed junco. Using this data as a basis for the case, several modules were written that would be applicable to a variety of biology courses. The case was first tested in a one semester General Biochemistry course, as an introduction to Genomics and Bioinformatics. Student feedback was positive and students were excited to be able to explore this new topic using hands on investigation. Also to be included in this case are modules that will be tested in an Anatomy and Physiology course. The case is planned to be submitted to the SUNY Case Study Library later this year.

### Case Activity (selected)

**Introduction**

...Historically, scientists thought that most bird species had fewer olfactory neurones, which means that their sense of smell is reduced. Therefore, it was assumed that chemical communication in birds, such as the use of pheromones for mate selection or species recognition, was essentially nonexistent. However, new research conducted by Dr. Danielle Whitaker ... indicate that birds do indeed have a sense of smell. Also, chemical compounds found in the preen oil of various passerine bird species, is used for assessing potential mates and has been linked to reproductive success. (1)

**Pheromones and Steroid Biochemistry**

(Using Figure 1 – all activity questions indicated in purple italics) What component is in the most abundant in female juncos? In male juncos?

What component is in the highest proportion when looking at the preen oil composition in female juncos? In male juncos?

**Genomics and Bioinformatics Exploration**

...Compounds in preen oil have been linked to mate selection and reproductive success. Additional research done by Dr. Rosvall's group have investigated hormones in birds from a biochemical and genomics perspective (2). Several of the species they investigate are known to have diverged over the last 10-15,000 years with respect to several testosterone-mediated traits, including aggression, ornamentation, and body size. Their work looked at gene expression along the steroid biosynthetic pathway.

### Survey Results

- **Able to recall major concepts (pheromone, main gene family)**
  - The query is the so called sequence we were looking at. The subject was of others that were being compared to the query that showed similarities among the results of the query search.
- **Helpful in learning/achieved learning goals**
  - Using the BLAST was helpful in understanding the process of analyzing data.
  - It was helpful/useful to learn about the BLAST search as I had never heard of it prior to this. It is interesting to be able to identify and compare different birds sequences to one another.
  - The self-guided nature of it was helpful, learning about it at your own pace and being responsible for your own results.

### Discussion

On the whole, students seemed to find the case interesting, easy to follow, and that it improved their ability to conduct and analyze a BLAST search, as well as learn about bird pheromones. As these were two of the objectives, this is very promising for this case. Students seemed to be able to recall accurately several key aspects of the case which points to its success. Overall students seem to feel this was a valuable learning activity and were fully engaged.

While students mentioned needing more instruction on BLAST and the steroid biochemistry pathway, it seems that this may be due to a lack of understanding the objective of an inquiry driven case method approach and this case in particular. Such an approach would be followed up in future activities to explore and discuss further. This case was designed as a means to introduce students to this basic Bioinformatic tool and would be followed up with more discussion.

Students were confused by the steroid biosynthetic pathway, so it may benefit from a better description and editing of some of those questions. There are different levels of questions/tasks built into the activity purposefully, and more guidance on the depth of information/reflection desired would be helpful in improving the case.

### Future Work

Improvements to questions and some supplemental explanations will be made based on observations and survey results to the case as it was presented. Dr. Haswell is also planning on piloting several other modules of this case, as well as the introduction in her Anatomy and Physiology courses later this year.

### Acknowledgements

This work was supported by a Science CaseNet Fellowship (NEI RCS U54 Grant #134428). Many thanks to the QUBES/BIOQUEST organizers for providing the community and opportunity to develop this case. Thanks to Pat Masteller for her wonderful mentorship. Thanks to our students for piloting this case activity and providing very valuable feedback.
